

Fedena Integration — Questions for the Vendor

1. How Fedena is set up for MP

- 1.1. Is the whole state on one shared Fedena instance, or does each university / college have its own separate Fedena? This decides whether we talk to one API or many.
- 1.2. If it is one shared instance, how do we tell institutions apart in the API (an institution ID, a subdomain, something else)? And will a single set of API credentials let us read data for all institutions, or is it locked to one at a time?
- 1.3. Roughly how much data are we talking about — how many colleges, how many staff, and how many students across the state?
- 1.4. Is this the standard Fedena product, or a customised / on-prem build for the state? And does the live API match the public docs at apis.fedena.com, or has it been changed or extended?

2. What the API gives us for each master

For each of these — colleges, departments, courses/programs, batches, subjects, students, employees/faculty, designations, users and roles:

- 2.1. Is there an endpoint to list all of them and another to fetch one by ID? Could you share the actual path and a sample response for each?
- 2.2. What is the unique ID we should rely on for each record, and does it stay the same over the years?
- 2.3. Do the records carry their relationships in the payload (for example, does a student record already include the college, course, batch and semester), or do we have to make separate calls to stitch that together?
- 2.4. Do we also get inactive records — passed-out students, transferred or left staff — and how are they marked? Or do they simply disappear from the list?
- 2.5. Is there anything in the list above that the standard API does not cover today and would need custom work?

3. Matching Fedena's structure to ours

- 3.1. Fedena usually works as Institution → Course → Batch. On our side we need University → College → Department → Program → Semester → Academic Year. Does Fedena give us the university-above-college level, the department, and the semester, or do we derive those ourselves? And how is academic year handled?
- 3.2. For people: is there one single user/login record, or are students and employees kept as separate masters with their own IDs? And how do we know what role someone has (HOD, principal, faculty, exam section, student)?
- 3.3. Does Fedena expose the specific things our exam process needs — admission number, roll/enrollment number, employee code, designation, which department a person belongs to, the course-batch-semester a student is in, and which subjects a faculty member is assigned to?

4. Login and single sign-on

- 4.1.** Do you support single sign-on, so that a Fedena user can come into our app without a second password? If yes, what method — SAML, OAuth/OIDC, or a token handoff / redirect?
- 4.2.** If there is no SSO, how do you suggest we handle login? We would prefer not to store passwords on our side. In that case, which detail should we trust to match a user — email, the Fedena user ID, or the employee / admission number?
- 4.3.** When someone is added, deactivated, or has their role changed in Fedena, how should that reach our login — immediately, or only at the next sync?

5. Keeping the two systems in sync

- 5.1.** Can we pull only what has changed (something like an 'updated since' filter or a change log), or do we have to pull the full list every time?
- 5.2.** Do you have webhooks that notify us when something is created, updated or deleted? If so, which events, what does the payload look like, what happens on retry, and how do we verify the call really came from you?
- 5.3.** For the very first load — bringing in lakhs of records across the state — what do you recommend, and is there a bulk export for that? How often would you suggest we sync after that?
- 5.4.** How are deletes, merges and transfers shown (a student moving college, a faculty member being reassigned), so that we don't end up with orphaned records on our side?

6. Limits and performance

- 6.1.** How does paging work (page numbers or cursors), and what is the biggest page size you allow?
- 6.2.** Are there rate limits per credential, and what happens if we hit them? For a statewide nightly sync, roughly what throughput can we count on?
- 6.3.** Are there maintenance windows or off-peak hours you would prefer we use for the heavy exports?

7. Errors, reliability and a place to test

- 7.1.** What does an error response look like, and how do we tell apart an auth problem, a bad request, and a server-side failure?
- 7.2.** Is there an uptime commitment or a status page we can watch?
- 7.3.** Is there a sandbox or staging Fedena with sample MP data that we can build and test against before we touch production?
